SPECIAL SCIENTIFIC REPORT-FISHERIES No. 289

UNITED STATES DEPARTMENT OF THE INTERIOR  
FISH AND WILDLIFE SERVICE

### Explanatory Note

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for the official use of Federal, State, or cooperating Agencies and in processed form for economy and to avoid delay in publication.

## A B S T R A C T

This report presents original data giving enumerations of the red tide organism, Gymnodinium breve, and associated chemical and hydrographic data for the period from February 1954 to July 1957. Methods of collecting and analyzing samples are described. It contains counts of G. breve, data on salinity, pH, copper, inorganic phosphorus, total phosphate, nitrate-nitrite, carbohydrates, and protein equivalents. These data were collected as part of a study on the distribution and incidence of G. breve, and related ecological conditions.

COUNTS OF RED TIDE ORGANISMS, Gymnodinium breve, AND ASSOCIATED  
OCEANOGRAPHIC DATA FROM FLORIDA WEST COAST, 1954-57

Extensive fish kills have occurred frequently in recent years, in the waters along the southwest Florida coast, accompanied by areas of discolored water. This condition, commonly known as red tide, is caused by blooms of the dinoflagellate Gymnodinium breve, Davis.

Earlier outbreaks of red tide have been described by Galtsoff (1948), Gunter et al. (1948), Lackey and Hynes (1955), Wilson and Ray (1956), and others. A bibliography of red tides in Florida waters was compiled by Hutton (1956).

Since the identification of G. breve in 1947, field studies have been conducted by the U. S. Fish and Wildlife Service to determine its incidence and distribution in Gulf coastal waters and to expand existing knowledge of associated ecological conditions. The phosphorus content of these waters from May 1949 through January 1951 has been published by the Service (Graham, Amison, and Marvin 1954). This was followed by a report on the oceanographic observations from May 1949 through July 1951 (Marvin 1955a). In continuation of the policy of publishing original data for the use of research agencies or individuals interested in the red tide problem, this report presents in tabular form the original hydrographic and biological observations for the period from February 1954 to July 1957.

The field work was discontinued from 1952 until it was resumed by the Service in early 1954, but laboratory work on the culture of G. breve was started in the interim. For some results of this work see Ray and Wilson (1957).

The sampling stations (figs. 1-5) extend approximately 210 miles along the Florida coast chiefly in the coastal and offshore waters from Clearwater to Marathon. The station locations, except for some that are in upstream rivers and canals, are in areas in which high concentrations of G. breve were found. Most stations fall within the 10-fathom line.

During the period covered by these data there was little red tide activity. The outbreak of 1952 was past, and the 1953-54 surge was on the wane in 1955; from January 1955 through June 1957 no outbreaks were recorded.

## METHODS

### Sampling techniques

At the start of intensive field sampling in 1954, limited information was available on which to base techniques for G. breve sampling. Consequently, sampling equipment and methods have undergone changes to conform with expanding knowledge of the organism.

Sampling was chiefly from the research vessel Kingfish, a 43-foot, twin-screw diesel cruiser, equipped with depth recorder and radar. Samples have also been collected with smaller boats, and a seaplane was used extensively to reach shallow bays and other less accessible spots. Stations on canals and some at beaches and rivers have been sampled from the shore or bank.

Initially, surface water samples were taken with a galvanized iron bucket and subsurface samples by use of a 3-liter modified Kemmerer sampler. To eliminate possible metallic contamination of the samples a polyethylene bucket has been in use since October 1954 for surface samples. The subsurface sampler was replaced by a weighted polyethylene container in November 1954.

Immediately upon collection of a sample, water temperature was measured with a mercury centigrade thermometer to the nearest tenth of a degree. The hydrogen ion concentration was measured with either a portable Coleman pH meter or a pocket-size model manufactured by the Analytical Measurement Company, Inc.

Water samples for estimation of G.

breve abundance were poured from the collection container into 2-liter Erlenmeyer flasks previously rinsed with a small amount of the sample water. During periods of high air temperature, wet newspaper was placed around the flasks to maintain a stable temperature. Pieces of polyethylene sheeting were placed over the mouth and secured to the flask neck with rubber bands to prevent spillage or contamination.

Water samples for salinity analysis were collected at all stations in 4-ounce Duraglass prescription bottles. Pyrex glass bottles of 250 ml. capacity with glass stoppers were used to collect water samples for copper analysis. Total phosphorus, inorganic phosphate, nitrate-nitrite, and carbohydrate and protein equivalents were determined from quick-frozen samples collected in 200 by 25 mm. pyrex glass culture tubes, fitted with polyethylene or polyethylene-lined screw caps. All containers used for sampling were chemically cleaned prior to use, and, after collection of the water sample, were sealed with plastic electrical tape for later analysis.

#### Enumeration of *Gymnodinium breve*

Water samples for *G. breve* analysis were usually examined within 24 hours after collection. Most of the samples were concentrated (the organisms given time to move to the surface of the sample) under 40-watt fluorescent lights, but available lighting was also used when a return to the field station was not feasible. Satisfactory concentration of the organism was obtained with lights from 8 to 18 inches above the flasks. The period of concentration at room temperature under ordinary conditions was ideally 16-18 hours, preferably overnight, and a minimum concentration period of 4 hours was observed.

Examination of sample aliquots for the living organisms was made with a stereoscopic, wide-field, inclined binocular microscope equipped with 18X wide-field eyepieces. The technique was as follows:

1. After the samples had been concentrated, three to six 1-milliliter aliquots were pipetted from the area just beneath the surface of the water sample and each deposited in the depression of a 3-depression micro-plate. If no *G. breve*

were found in these aliquots, the water sample was assumed to contain no *G. breve* and the count was recorded as none.

For general detection and for counting of both concentrated and mixed samples, magnifications of 54X and 144X were used.

2. If *G. breve* were observed in the initial concentrated aliquots, the flask was inverted several times to redistribute the organisms throughout the sample of water. Then, depending on the numbers of *G. breve* per milliliter (1-99; 100-1000; or more than 1000) in the examination of concentrated samples, 1.0 ml., 0.1 ml., or 0.01 ml. aliquot was pipetted from within the flask to each of 3 depressions in a micro-plate. The number of *G. breve* observed per milliliter or fraction was then recorded for each of the 3 aliquots. If the count did not agree in 2 out of 3 of these aliquots, an additional 3 aliquots were drawn from the flask and examined. The numbers of *G. breve* for all aliquots were averaged and shown as the number per milliliter of water. In cases where *G. breve* were found in the surface layer of a concentrated sample, usually in very low numbers, but not in the mixed, or when no counts were made of a mixed (or agitated) sample, the symbol P is used to indicate that the organism was present.

Counts were of the living organism; no preserved or fixed specimens were used. The counting technique assumes that after several inversions of the flask *G. breve* are randomly distributed. Until counts of such agitated samples were instigated in 1955, however, most of the concentrated samples were merely given an adjective rating for abundance.

#### Chemical analyses

Salinities were determined by the Mohr-Knudsen method described by Knudsen (1901). Nitrate-nitrite determinations were made by the method of Zwicker and Robinson (1944) as modified by Marvin (1955b).

The method of Robinson and Thompson (1948) was used to determine amounts of inorganic phosphates and the method of Harvey (1948) was used in total phosphorus determinations. Copper determinations were by the analytical method of Hoste,

Eeckhout and Gillis (1953).

Arabinose equivalents of carbohydrates were determined by the N-ethyl-carbazole method of Erdman as modified by Zein-Eldin and May (1958).

Tyrosine equivalents of protein content were determined by a method developed by Peter J. Wangersky as modified by Zoula P. Zein-Eldin and B. Z. May in which the amino-acid content equivalent to tyrosine is obtained by hydrolysis in 0.375 N sodium hydroxide solution.

The determination is carried out as follows:

1. Thaw frozen samples.
2. Pipette duplicate 20-ml. samples with a volumetric pipette into 50-ml. glass reagent bottles with ground glass stoppers.
3. Add 20 ml. of 0.75 N sodium hydroxide from an automatic burette.
4. Autoclave at 80 pounds for 2-3 hours.
5. Centrifuge for 20 minutes.
6. Read on the Beckman spectrophotometer, using the optical density scale. Set wave length at 330 m $\mu$  and use the ultra-violet light source. Use the 5 cm. silica cells and read against distilled water.
7. Treat blanks and samples of tyrosine (1, 3, 5, mg. per liter) similarly. Blanks are made up in protein-free artificial sea water. Standards are made up in a low protein natural sea water, if available; otherwise, artificial sea water is used.

#### ACKNOWLEDGMENT

The authors are indebted to numerous co-workers for their advice and assistance in assembling the data contained in this report. K. T. Marvin, Z. Zein-Eldin, B. Z. May and L. Lansford made the chemical analyses and determinations. M. W. Jambor assisted in enumeration of G. breve and in tabulating data.

Albert W. Collier developed the sampling methods and William B. Wilson developed the enumeration techniques. Joe O.

Bell was in charge of the field work until March 1957.

The Florida State Board of Conservation, especially Ernest Mitts, Director, Robert M. Ingle and Dr. Robert F. Hutton cooperated in numerous instances by supplying patrol vessels and crews and other facilities.

#### EXPLANATION OF COLUMN HEADINGS

Time	Eastern Standard Time.	flask to distribute organisms at random.
S or B	Surface or bottom (occasionally M for mid-depth and actual depth in feet).	Sal. Salinity in parts per thousand.
C.	Concentrated sample. Shows absence (0), or presence (P) when no mixed counts were taken, of live cells in 3 (or 6) 1 ml. aliquots pipetted from surface of a 2-liter water sample after exposure from 4 to 24 (or more) hours to artificial light (usually 40-watt fluorescent lamp 8 to 18 inches above surface of sample). P may also indicate that live cells were present in the concentrated sample when none were found in the mixed samples.	Cu. Copper, µg-at/L. PO <sub>4</sub> Phosphate. In. Inorganic phosphate. µg-at PO <sub>4</sub> - P/L Tot. Total phosphate. µg-at PO <sub>4</sub> - P/L
M.	Mixed sample. Average number of live cells per ml. in 3 (or 6) 1 ml. aliquots from near center of 2-liter water sample after several inversions of sample	NO <sub>3</sub> - NO <sub>2</sub> Nitrogen. µg-at NO <sub>3</sub> - NO <sub>2</sub> - N/L Car. Carbohydrates. mg/L arabinose equivalents. Pro. Proteins. mg/L tyrosine equivalents.
